

OneChain

AI + RWA Institutional Whitepaper

Full-Stack Infrastructure for Tokenized Real-World and AI Assets

Hybrid Consensus: PoS + Authority | 101 Validators

20,000+ TPS | 1 Second Block Time

Native Stablecoin Gas | AGI Governance Token

Version 1.0 — 2025-01-28

Executive Summary

The tokenization of real-world assets represents one of the most significant structural shifts in financial infrastructure in decades. Traditional capital markets remain fragmented and dependent on multiple intermediaries. Tokenization introduces programmable ownership, automated settlement, and global investor access. Through these capabilities, assets that were previously illiquid or geographically constrained can become globally tradable financial instruments.

The OneChain decentralized exchange introduces a hybrid liquidity architecture combining automated market makers with orderbook settlement infrastructure. This design allows retail participants to access continuous liquidity while enabling institutional participants to execute large trades through structured orderbook mechanisms. Liquidity pools support programmable market making, while orderbook settlement provides price discovery for tokenized assets.

Security within tokenized financial infrastructure requires layered protections including validator slashing, multi-signature treasury controls, audited smart contracts, and proof-of-reserve mechanisms for tokenized assets. OneChain integrates these protections directly into the protocol architecture to ensure that both digital assets and tokenized real-world assets remain secure and transparently verifiable within the network.

Artificial intelligence introduces an additional layer of economic infrastructure built around compute resources, machine learning models, and data marketplaces. These AI-native assets may be tokenized, traded, and integrated into financial markets. By supporting tokenized AI infrastructure, OneChain enables the creation of programmable digital economies in which compute resources, algorithmic services, and data assets become financial primitives within a global decentralized network.

As global financial markets increasingly adopt tokenization technologies, infrastructure platforms capable of supporting large-scale asset issuance and trading will become foundational components of the digital financial system. OneChain is designed to serve as a global infrastructure layer connecting traditional financial assets, AI-driven digital economies, and decentralized financial markets within a unified programmable protocol.

OneChain is designed as a global financial infrastructure platform connecting tokenized real-world assets, AI-native digital assets, and decentralized capital markets. The protocol provides a scalable blockchain network capable of supporting institutional settlement systems, digital asset issuance, decentralized exchanges, and tokenized investment markets. By combining blockchain infrastructure with programmable finance, OneChain enables global investors and institutions to participate in digitally native financial markets with improved transparency, automation, and efficiency.

The OneChain network architecture is designed to support high throughput and deterministic finality required for institutional financial infrastructure. A hybrid Proof-of-Stake and Authority consensus mechanism balances decentralization, performance, and security. Validators participate in block production, while authority validators finalize blocks, ensuring fast and reliable settlement suitable for asset trading and financial applications.

Governance within the OneChain ecosystem is coordinated through the AGI governance token. AGI holders participate in decentralized decision-making regarding protocol upgrades, validator policies, treasury allocation, and ecosystem development initiatives. By separating governance from transaction fees, the protocol ensures stable transaction costs while enabling long-term governance participation across the network.

The economic model of the OneChain ecosystem aligns incentives between validators, developers, institutions, and investors. Protocol revenue generated through settlement fees, asset issuance fees, and exchange trading activity flows into a treasury pool governed by AGI token holders. Treasury allocations fund ecosystem development, validator incentives, and infrastructure expansion across the network.

As global financial markets increasingly adopt tokenization technologies, infrastructure platforms capable of supporting large-scale asset issuance and trading will become foundational components of the digital financial system. OneChain is designed to serve as a global infrastructure layer connecting traditional financial assets, AI-driven digital economies, and decentralized financial markets within a unified programmable protocol.

Industry Background

The tokenization of real-world assets represents a major structural shift in financial infrastructure. Traditional capital markets remain fragmented and dependent on multiple intermediaries. Tokenization introduces programmable ownership, automated settlement, and global investor access, enabling previously illiquid or geographically constrained assets to become globally tradable financial instruments.

Tokenized asset markets require additional infrastructure beyond standard blockchain networks. Compliance verification, custody frameworks, asset registries, and legal structuring mechanisms must operate alongside consensus systems. OneChain integrates these components directly into the protocol layer, creating a unified financial infrastructure stack capable of supporting institutional asset issuance and decentralized market liquidity.

The OneChain decentralized exchange employs a hybrid liquidity architecture combining automated market makers with orderbook settlement infrastructure. This design allows retail participants to access continuous liquidity while enabling institutional participants to execute large trades through structured orderbook mechanisms. Liquidity pools support programmable market making, while orderbook settlement provides price discovery for tokenized assets.

Security within tokenized financial infrastructure requires layered protections including validator slashing, multi-signature treasury controls, audited smart contracts, and proof-of-reserve mechanisms. OneChain integrates these protections directly into the protocol architecture to ensure both digital assets and tokenized real-world assets remain secure and transparently verifiable.

Artificial intelligence introduces an additional layer of economic infrastructure built around compute resources, machine learning models, and data marketplaces. These AI-native assets may be tokenized, traded, and integrated into financial markets. By supporting tokenized AI infrastructure, OneChain enables the creation of programmable digital economies in which compute resources, algorithmic services, and data assets become financial primitives within a global decentralized network.

The OneChain network architecture is designed to support high throughput and deterministic finality required for institutional financial infrastructure. A hybrid Proof-of-Stake and Authority consensus mechanism balances decentralization, performance, and security. Validators participate in block production while authority validators finalize blocks, ensuring fast and reliable settlement suitable for asset trading and financial applications.

Governance within the OneChain ecosystem is coordinated through the AGI governance token. AGI holders participate in decentralized decision-making regarding protocol upgrades, validator policies, treasury allocation, and ecosystem development initiatives. By separating governance from transaction fees, the protocol ensures stable transaction costs while enabling long-term governance participation.

The economic model of the OneChain ecosystem aligns incentives between validators, developers, institutions, and investors. Protocol revenue generated through settlement fees, asset issuance fees, and exchange trading activity flows into a treasury pool governed by AGI token holders. Treasury allocations fund ecosystem development, validator incentives, and infrastructure expansion across the network.

As global financial markets increasingly adopt tokenization technologies, platforms capable of supporting large-scale asset issuance and trading will become foundational components of the digital financial system. OneChain is designed to serve as a global infrastructure layer connecting traditional financial assets, AI-driven digital economies, and decentralized financial markets within a unified programmable protocol.

Global Market Opportunity

As global financial markets increasingly adopt tokenization technologies, infrastructure platforms capable of supporting large-scale asset issuance and trading will become foundational components of the digital financial system. OneChain is designed to serve as a global infrastructure layer connecting traditional financial assets, AI-driven digital economies, and decentralized financial markets within a unified programmable protocol.

The tokenization of real-world assets represents a major structural shift. Traditional capital markets remain fragmented and dependent on multiple intermediaries. Problem Statement

OneChain is designed as a global financial infrastructure platform connecting tokenized real-world assets, AI-native digital assets, and decentralized capital markets. The protocol provides a scalable blockchain network capable of supporting institutional settlement systems, digital asset issuance, decentralized exchanges, and tokenized investment markets. By combining blockchain infrastructure with programmable finance, OneChain enables global investors and institutions to participate in digitally native financial markets with improved transparency, automation, and efficiency.

The economic model of the OneChain ecosystem aligns incentives between validators, developers, institutions, and investors. Protocol revenue generated through settlement fees, asset issuance fees, and exchange trading activity flows into a treasury pool governed by AGI token holders. Treasury allocations fund ecosystem development, validator incentives, and infrastructure expansion across the network.

Tokenized asset markets require infrastructure beyond standard blockchain networks. Compliance verification, custody frameworks, asset registries, and legal structuring mechanisms must operate alongside consensus systems. OneChain integrates these components directly into the protocol layer, creating a unified financial infrastructure stack capable of supporting institutional asset issuance and decentralized market liquidity.

The OneChain decentralized exchange employs a hybrid liquidity architecture combining automated market makers with orderbook settlement infrastructure. This design allows retail participants to access continuous liquidity while enabling institutional participants to execute large trades through structured orderbook mechanisms. Liquidity pools support programmable market making, while orderbook settlement provides price discovery for tokenized assets.

Security within tokenized financial infrastructure requires layered protections including validator slashing, multi-signature treasury controls, audited smart contracts, and proof-of-reserve mechanisms. OneChain integrates these protections directly into the protocol architecture to ensure that both digital assets and tokenized real-world assets remain secure and transparently verifiable within the network.

Artificial intelligence introduces an additional layer of economic infrastructure built around compute resources, machine learning models, and data marketplaces. These AI-native assets may be tokenized, traded, and integrated into financial markets. By supporting tokenized AI infrastructure, OneChain enables the creation of programmable digital economies in which compute resources, algorithmic services, and data assets become financial primitives within a global decentralized network.

Compliance verification, custody frameworks, asset registries, and legal structuring mechanisms operate alongside consensus systems. OneChain integrates these components directly into the protocol layer, creating a unified financial infrastructure stack capable of supporting institutional asset issuance and decentralized market liquidity.

The OneChain network architecture is designed to support high throughput and deterministic finality required for institutional financial infrastructure. A hybrid Proof-of-Stake and Authority consensus mechanism balances decentralization, performance, and security. Validators participate in block production while authority validators finalize blocks, ensuring fast and reliable settlement suitable for asset trading and financial applications.

Security within tokenized financial infrastructure requires layered protections, including validator slashing, multi-signature treasury controls, audited smart contracts, and proof-of-reserve mechanisms for tokenized assets. OneChain integrates these protections

directly into the protocol architecture to ensure that both digital assets and tokenized real-world assets remain secure and transparently verifiable within the network.

The economic model of the OneChain ecosystem aligns incentives between validators, developers, institutions, and investors. Protocol revenue generated through settlement fees, asset issuance fees, and exchange trading activity flows into a treasury pool governed by AGI token holders. Treasury allocations fund ecosystem development, validator incentives, and infrastructure expansion across the network.

Governance within the OneChain ecosystem is coordinated through the AGI governance token. AGI holders participate in decentralized decision-making regarding protocol upgrades, validator policies, treasury allocation, and ecosystem development initiatives. By separating governance from transaction fees, the protocol ensures stable transaction costs while enabling long-term governance participation across the network.

Artificial intelligence introduces an additional layer of economic infrastructure built around compute resources, machine learning models, and data marketplaces. These AI-native assets may be tokenized, traded, and integrated into financial markets. By supporting tokenized AI infrastructure, OneChain enables the creation of programmable digital economies in which compute resources, algorithmic services, and data assets become financial primitives within a global decentralized network.

AGI Tokenomics

The OneChain network architecture is designed to support high throughput and deterministic finality required for institutional financial infrastructure. A hybrid Proof-of-Stake and Authority consensus mechanism balances decentralization, performance, and security. Validators participate in block production while authority validators finalize blocks, ensuring fast and reliable settlement suitable for asset trading and financial applications.

Governance within the OneChain ecosystem is coordinated through the AGI governance token. AGI holders participate in decentralized decision-making regarding protocol upgrades, validator policies, treasury allocation, and ecosystem development initiatives. By separating governance from transaction fees, the protocol ensures stable transaction costs while enabling long-term governance participation across the network.

The economic model of the OneChain ecosystem aligns incentives between validators, developers, institutions, and investors. Protocol revenue generated through settlement fees, asset issuance fees, and exchange trading activity flows into a treasury pool governed by AGI token holders. Treasury allocations fund ecosystem development, validator incentives, and infrastructure expansion across the network.

The OneChain decentralized exchange employs a hybrid liquidity architecture combining automated market makers with orderbook settlement infrastructure. This design allows retail participants to access continuous liquidity while enabling institutional participants to execute large trades through structured orderbook mechanisms. Liquidity pools support programmable market making, while orderbook settlement provides price discovery for tokenized assets.

The tokenization of real-world assets represents a major structural shift in financial infrastructure. Tokenization introduces programmable ownership, automated settlement, and global investor access, enabling previously illiquid or geographically constrained assets to become globally tradable financial instruments. Tokenized asset markets require additional infrastructure beyond standard blockchain networks, including compliance verification, custody frameworks, asset registries, and legal structuring mechanisms. OneChain integrates these components directly into the protocol layer to create a unified financial infrastructure stack capable of supporting institutional asset issuance and decentralized market liquidity.

Security within tokenized financial infrastructure is ensured through layered protections including validator slashing, multi-signature treasury controls, audited smart contracts, and proof-of-reserve mechanisms for tokenized assets. OneChain integrates these protections directly into the protocol architecture to ensure that both digital assets and tokenized real-world assets remain secure and transparently verifiable within the network.

Artificial intelligence introduces an additional layer of economic infrastructure built around compute resources, machine learning models, and data marketplaces. These AI-native assets may be tokenized, traded, and integrated into financial markets. By supporting tokenized AI infrastructure, OneChain enables the creation of programmable digital economies in which compute resources, algorithmic services, and data assets become financial primitives within a global decentralized network.

Governance Framework

Governance within the OneChain ecosystem is coordinated through the AGI governance token. AGI holders participate in decentralized decision-making regarding protocol upgrades, validator policies, treasury allocation, and ecosystem development initiatives. By separating governance from transaction fees, the protocol ensures stable transaction costs while enabling long-term governance participation across the network.

The governance framework aligns incentives between validators, developers, institutions, and investors. Protocol revenue generated through settlement fees, asset issuance fees, and exchange trading activity flows into a treasury pool governed by AGI token holders. Treasury allocations fund ecosystem development, validator incentives, and infrastructure expansion, supporting the sustainable growth of the network.

OneChain integrates governance with its technical infrastructure, including a hybrid Proof-of-Stake and Authority consensus mechanism, which balances decentralization, performance, and security. Validators participate in block production while authority validators finalize blocks, ensuring fast and reliable settlement suitable for asset trading and financial applications.

The governance framework also ensures the security and transparency of tokenized assets. AGI holders oversee multi-layered protections such as validator slashing, multi-signature treasury controls, audited smart contracts, and proof-of-reserve mechanisms, maintaining network integrity and trustworthiness.

Through this governance structure, OneChain enables community-driven decision-making, transparent oversight of protocol operations, and long-term alignment of incentives, establishing a robust foundation for a scalable financial infrastructure connecting tokenized real-world assets, AI-native digital assets, and decentralized capital markets.

Security Architecture

OneChain is designed as a global financial infrastructure platform connecting tokenized real-world assets, AI-native digital assets, and decentralized capital markets. The protocol provides a scalable blockchain network capable of supporting institutional settlement systems, digital asset issuance, decentralized exchanges, and tokenized investment markets. By combining blockchain infrastructure with programmable finance, OneChain enables global investors and institutions to participate in digitally native financial markets with improved transparency, automation, and efficiency.

As global financial markets increasingly adopt tokenization technologies, infrastructure platforms capable of supporting large-scale asset issuance and trading will become foundational components of the digital financial system. OneChain is designed to serve as a global infrastructure layer connecting traditional financial assets, AI-driven digital economies, and decentralized financial markets within a unified programmable protocol.

The OneChain decentralized exchange introduces a hybrid liquidity architecture combining automated market makers with orderbook settlement infrastructure. This design allows retail participants to access continuous liquidity while enabling institutional participants to execute large trades through structured orderbook mechanisms. Liquidity pools support programmable market making while orderbook settlement provides price discovery for tokenized assets.

Tokenized asset markets require additional infrastructure beyond standard blockchain networks. Compliance verification, custody frameworks, asset registries, and legal structuring mechanisms must operate alongside consensus systems. OneChain integrates these components directly into the protocol layer, creating a unified financial infrastructure stack capable of supporting institutional asset issuance and decentralized market liquidity.

The tokenization of real-world assets represents one of the most significant structural shifts in financial infrastructure in decades. Traditional capital markets remain fragmented and dependent on multiple intermediaries. Tokenization introduces programmable ownership, automated settlement, and global investor access. Through these capabilities, assets that were previously illiquid or geographically constrained can become globally tradable financial instruments.

The OneChain network architecture is designed to support high throughput and deterministic finality required for institutional financial infrastructure. A hybrid Proof-of-Stake and Authority consensus mechanism allows the network to balance decentralization, performance, and security. Validators participate in block production while authority validators finalize blocks, ensuring fast and reliable settlement suitable for asset trading and financial applications.

Security within tokenized financial infrastructure requires layered protections, including validator slashing, multi-signature treasury controls, audited smart contracts, and proof-of-reserve mechanisms for tokenized assets.
